Magneetostrictive Iron-Gallium (FeGa) nanowires have tremendous potential as functional materials in micro and nano-transducers.

- A mechanism was proposed for electro-deposition of Fe-Ga alloys, and it was successfully used in fabricating reproducible FeGa/Cu multilayered nanowires (Fig. 1).

- FeGa/Cu nanowire arrays exhibits anisotropic or isotropic magnetic behavior depending on the architecture (Fig. 2).

Magnetic behavior can thus be tailored by varying the aspect ratio of ferromagnetic FeGa and non-magnetic Cu layers.
